FOREWORD

The Pond Dynamics/Aquaculture Collaborative Research Support Program (PD/A CRSP) represents an international community of researchers and institutions dedicated to strengthening health and nutrition in developing countries by improving the efficiency of pond aquaculture systems. It is one of several agricultural CRSPs supported by the U.S. Agency for International Development under the authority of Title XII of the International Development and Food Assistance Act of 1975.

The "Global Experiment" in Pond Dynamics/Aquaculture is the major CRSP research activity, covering the period from 1982 to 1987. The Global Experiment was designed to quantitatively describe the physical, chemical and biological principles of pond culture systems. The information gained from the Global Experiment will be used to improve production technologies and develop quantitative production functions to facilitate rigorous economic analyses of aquaculture systems.

Standardization is a key element of the Global Experiment. Standardization permits the comparison of data from diverse geographic locations. The experimental design involves monitoring specified environmental and fish production variables in accordance with standardized work plans in twelve or more ponds at each of seven geographical locations. The variables observed, frequency of observation, and materials and methods are uniform for all locations. The field data are filed in a centralized data base, called the CRSP Central Data Base. Statistical methods will be used to test hypotheses about correlations between variables and to evaluate the sources of variance within ponds, between ponds within locations, and between locations.

The CRSP Central Data Base will be used to develop predictive models of the processes occurring in pond culture systems. The models will be used to: provide guidance for ongoing and future research; predict the performance of existing and proposed pond systems subject to specific inputs and constraints; and improve the operation and efficiency of pond culture systems.

The Global Experiment includes three cycles of experiments. Each cycle consists of two series of observations, one during the dry season and one during the wet season. The objective of the first cycle is to create a detailed baseline of chemical, physical, and biological data on all ponds treated with a standard level of inorganic fertilizer. In the second experimental cycle, ponds treated with inorganic fertilizer are compared to ponds treated with organic fertilizer. In the third cycle, the responses of ponds to different levels of organic fertilizer are compared.

The goal of the Pond Dynamics/Aquaculture Collaborative Research Data Reports (referred to as Data Reports) is to record the CRSP Central Data Base and to present interpretations of site specific results. The Pond Dynamics/Aquaculture CRSP has conducted the Global Experiment at seven project sites in six developing countries: Thailand, Indonesia, the Philippines, Panama, Honduras, and Rwanda. The first volume of these reports provides descriptive information for each CRSP site. It presents the physical characteristics of each site, including a geographical sketch, climatology, and water and soil analyses. Experimental cycles are described in CRSP Work Plans One to Three, which are summarized in the first volume.

Volume One will serve as the reference volume for the entire report series. Subsequent volumes will focus on each site separately. Each Data Report will include one cycle (wet and dry seasons) of the Pond Dynamics/Aquaculture CRSP Global Experiment. Therefore, with few exceptions, each project site will have three Data Reports devoted to it, representing the results of the three cycles of the Global Experiment. Cycle II of the Global Experiment in Honduras is presented in this volume.

INTRODUCTION

Cycle II Pond Dynamics/Aquaculture (PD/A) CRSP research continued to investigate the addition of nutrients to tilapia production ponds in the tropics. Chemical fertilization with phosphorus only was tested during the dry and rainy seasons of the Cycle I CRSP research, and tilapia yield in Honduras was less than half that expected (Green et al., 1985). High levels of clay turbidity in the water inhibited primary productivity and, consequently, fish production (Green et al., 1985). Organic fertilizers stimulate primary and secondary productivity in ponds, and also can mitigate the detrimental effects of clay turbidity. The objective of Cycle II CRSP research was to test the hypothesis that organic and inorganic fertilization result in the same fish production. In addition, dry and rainy season results were compared.

MATERIALS AND METHODS

Twelve 0.1-ha earthen ponds at the El Carao Aquacultural Experiment Station, Comayagua, Honduras, were used during this study. Dry season treatments (4 replicates/treatment) were layer chicken litter, dairy cow manure, and urea plus triple superphosphate. Rainy season treatments (6 replicates/treatment) were chicken litter and urea plus triple superphosphate. Chicken litter, obtained from a local commercial layer operation, was purchased in bulk for each experiment and stored in woven plastic sacks under cover until it was broadcast over the pond surface. Cow manure was obtained from the dairy on the Recursos Naturales Agricultural Experiment Station, Comayagua. Fresh manure was scraped from the milking parlor beginning Saturday and continuing through Monday morning, when it was applied. The cow manure was mixed with pond water to make a thick slurry which was poured into the pond along one edge. Manure total solids was determined prior to each fertilization, and wet weight was corrected accordingly. The nitrogen, phosphorus, potassium and organic matter contents of the manure were determined using methods given in Jackson (1958).

Male *Oreochromis niloticus* fingerlings were stocked into ponds at a rate of 10,000/ha. At stocking, fingerlings averaged 32.9 g and 16.7 g, during the dry and rainy seasons, respectively. The dry season experiment was initiated on 16 January 1985, and all ponds were harvested on 15 June 1985, 150 days after stocking. Ponds for the rainy season experiment were stocked on 26 July 1985 and harvested on 23 December 1985, 150 days later. Ponds were managed according to guidelines given in Egna et al. (1987).

Selected water chemistry variables were determined on a weekly or monthly basis, meteorological variables measured 5 days per week, and initial and final water and mud samples were analyzed (see Egna et al., 1987). Exceptions to the prescribed methods were: ammonia (dry and rainy seasons) was analyzed using the phenate method (APHA, 1980); chlorophyll a (dry season), Kjeldahl nitrogen (both seasons) and nitrate (dry season) were not analyzed due to lack of either equipment or reagents. Primary productivity was determined monthly utilizing

the free-water diurnal curve method (Hall and Moll, 1975); measurements were made at 4-hour time and at 0.25-m depth intervals. Measured values were corrected for oxygen diffusion across the air-water interface using an empirical relationship relating the oxygen transfer coefficient to wind speed (Banks and Herrera, 1977).

Pond mud samples were collected according to the CRSP Second Work Plan (undated). Initial dry season samples, final dry season samples (which also served as the initial rainy season samples), and the final rainy season samples were analyzed at a soils laboratory in Honduras. Initial and final water samples for the dry and rainy season experiments were collected from each pond, preserved according to the CRSP Second Work Plan, and analyzed for major/minor elements. The final dry season water samples were inadvertently discarded.

Data were analyzed using analysis of variance, 2-factor analysis of variance (where the factors were treatment and season), t-test, and regression analysis using the StatView SE + Graphics statistical data analysis package (Feldman et al., 1988). The cow manure treatment was excluded from seasonal comparisons. Data were reported as means by pond, and means \pm standard error. Differences were declared significant at an alpha level of 0.05.

RESULTS

FISH YIELD

During the dry season, the mean fish yield was significantly greater in the chicken litter treatment (2075 ± 89 kg/ha) than in the other treatments, but yield of the dairy cow manure (1626 ± 39 kg/ha) and chemical fertilizer (1194 ± 106 kg/ha) treatments were not significantly different (Tables 1 and 2, Figure 1). During the rainy season, tilapia yield was significantly greater in the chicken litter treatment (1426 ± 71 kg/ha) than in the chemical fertilizer treatment (987 ± 96 kg/ha) (Tables 1 and 2, Figure 2). Chicken litter applications also resulted in significantly greater tilapia yield than did chemical fertilizer applications when dry and rainy season data were combined (Table 3). Significant seasonal differences were detected only for tilapia yield, which was due to the significantly lower rainy season initial biomass (Table 3). Total net yield and net daily yield were not significantly different between seasons (Table 3).

WATER QUALITY VARIABLES

Results of water quality analyses are summarized by pond in Table 4, and by season in Figures 3 to 14. Seasonal water quality means are compared in Table 5.

BIOLOGICAL VARIABLES

Primary Productivity and Community Respiration

Net and gross primary productivity during the dry season were similar in the chicken litter and chemical fertilizer treatments (Table 6). Dry season community respiration in the chicken litter treatment was significantly greater than in the chemical fertilizer treatment (Table 6). Rainy season net and gross primary productivity, and community respiration were significantly greater in the chicken litter treatment than in the chemical fertilizer treatment (Table 6). When means for the chicken litter and chemical fertilizer treatments were compared across seasons, all measures of primary productivity were significantly greater for the chicken litter treatment (Table 7). Net primary productivity and community respiration were significantly greater during the rainy season (Table 7).

Secchi Disk Visibility

Mean dry season Secchi disk visibilities (SDV) were 15.1 cm, 17.7 cm, and 15.0 cm for the chicken litter, cow manure, and chemical fertilizer treatments, respectively. The cow manure mean SDV was significantly greater than the other treatment means. During the rainy season, mean SDV for the chicken litter treatment (20.6 cm) was significantly greater than that for the chemical fertilizer treatment (13.6 cm).

Chlorophyll a

Mean chlorophyll a concentrations ranged from 79.4 to 613.1 mg/m³ during the rainy season. The mean chlorophyll a concentration in the chemical fertilizer treatment was 201.06 mg/m³, significantly greater than the 102.33 mg/m³ in the chicken litter treatment. The chlorophyll a concentration in pond B-5 was consistently much greater than in the other ponds of the chemical fertilizer treatment. When B-5 data were excluded, the mean chlorophyll a concentration for the chemical fertilizer treatment (121.0 mg/m³) was not significantly different from the chicken litter treatment (102.4 mg/m³) (Figure 15).

NUTRIENT ADDITIONS

The chicken litter used in this study was composed of pine sawdust, manure, waste feed, and feathers. Similar quantities of nitrogen and phosphorus were added to ponds during each season (Table 8). However, phosphorus could not be applied as cow manure at a rate similar to that of the other fertilizers due to this manure's higher N:P ratio.

SOIL ANALYSES

Pond mud total nitrogen and manganese concentrations decreased during the dry season (Tables 9 and 10). Phosphorus and zinc concentrations tended to increase in muds during the dry season, but tended to decrease during the rainy season (Tables 9, 10, and 11). Organic matter and total nitrogen concentrations also tended to decrease during the rainy season (Tables 10 and 11). No other significant changes in pond mud nutrient concentrations were noted. It should be noted that the final soil sample from one season was used as the initial sample for the following season as the turn-around-time was less than 1 month.

MINOR ELEMENTS IN WATER

Nutrient concentrations generally increased during the culture period (Tables 12, 13, and 14).

METEOROLOGICAL VARIABLES

Monthly meteorological data are summarized in Table 15. No seasonal difference in solar radiation was noted. Half as much rain fell during the dry season as during the rainy season. Wind speed and maximum air temperature means were significantly greater during the dry season.

RELATIONSHIPS AMONG VARIABLES

Tilapia yield increased significantly with increases in community respiration during the dry season experiment (Figure 16). Rainy season tilapia yield increased significantly with increases in primary productivity and community respiration (Figures 17 to 19). Gross primary productivity increased significantly during the rainy season as Secchi disk visibility increased (Figure 20); the observed relationship was the inverse of that expected due to the presence of clay turbidity in certain ponds which limited primary productivity. Secchi disk visibility was also significantly correlated with net ($r^2 = 0.616$) and gross ($r^2 = 0.714$) primary productivity. Chlorophyll *a* did not correlate significantly with either Secchi disk visibility or primary productivity.

DISCUSSION

Dairy cow manure and chemical fertilizer were equally effective nutrient sources in tilapia grow-out ponds, but chicken litter was the most productive when similar total amounts of nitrogen and phosphorus were added as each fertilizer type. Chicken litter reduced clay turbidity in pond water which resulted in greater primary productivity and greater fish yield. Tilapia yield for the chemical fertilizer treatment was greater than that reported for phosphorus-

only fertilization in Honduras (Green et al., 1986); however, greater quantities of phosphorus, in addition to nitrogen, were added to ponds in the present study. The increased tilapia yield could be due to the additional phosphorus or nitrogen, or to the form of nitrogen, i. e., urea, added. Urea liberates H^+ upon dissociation, which aids in the elimination of clay turbidity by coagulating and precipitating fine clay particles. Phytoplankton can then utilize the added nutrients for growth. No turbidity control was employed when phosphorus was the only nutrient added to ponds (Green et al., 1986).

There were pronounced differences between dry and rainy season climates in Honduras; however, the absence of seasonal differences in fish yield or for water quality observations indicated that the form of nutrient (organic versus inorganic) was more important as a source of variation. When phosphorus was the only nutrient added in Honduras (Cycle I experiments), seasonal differences were observed for water quality observations, primary productivity, and tilapia yield (Green et al., 1986). Ponds were not adequately prepared for fish culture during the Cycle I experiments, as indicated by significant amounts of clay turbidity. Severe, chronic clay turbidity limited primary productivity during Cycle I experiments, and the impact of planned treatments on water quality and tilapia yield was insignificant. Under these conditions, seasonal differences became more important than treatments as sources of variation. During the present (Cycle II) experiments, pond productivity was not impaired by clay turbidity, which allowed treatment effects to manifest themselves. As a result, treatment became more important than season as a source of variation.

¹ CL = chicken litter, CM = cow manure, CF = chemical fertilizer.

Table 5. Comparison of dry and rainy season water quality observations (means) in ponds fertilized with chicken litter or chemical fertilizer during Cycle II.

Treatment	pH	Total alkalinity mg/l CaCO ₃	Total hardness	Ammonia mg/l NH ₃ -N	Total phosphorus mg/l PO ₄ -P	Soluble orthophosphate mg/l PO ₄ -P
Chicken Litter						
Dry season	7.8	131.3	99.3	0.25	5.5	4.0
Rainy season	7.9	137.7	95.2	0.58	5.1	3.8
Chemical Fertilizer						
Dry season	8.5	66.3	47.0	0.56	9.5	6.5
Rainy season	7.9	64.4	49.6	0.67	13.8	10.1
Treatment means						
Chicken litter	7.9*	135.2*	96.9*	0.45*	5.3*	3.9*
Chemical fertilizer	8.0	65.1	48.5	0.62	12.1	8.7
Seasonal means						
Dry season	8.0	98.8	73.1	0.40*	7.5	5.2
Rainy season	7.9	101.0	72.4	0.62	9.5	6.9

* Means are significantly different ($P \leq 0.05$).

Table 6. Mean primary productivity (g C/m³ per day) and community respiration (g C/m³ per day) in ponds fertilized with chicken litter or chemical fertilizer during the Cycle II dry and rainy season experiments.

Season	Net primary productivity	Gross primary productivity	Community respiration
Dry Season			
Layer chicken litter	1.44 ± 0.29 a	3.40 ± 0.59 a	4.02 ± 0.66 a
Dairy cow manure	0.58 ± 0.16 b	2.20 ± 0.33 b	3.15 ± 0.89 ab
Chemical fertilizer	1.38 ± 0.50 a	2.82 ± 0.81 ab	2.87 ± 1.54 b
Rainy Season			
Layer chicken litter	1.89 ± 0.15 x	5.58 ± 0.33 x	7.38 ± 0.36 x
Chemical fertilizer	1.21 ± 0.17 y	3.54 ± 0.48 y	4.66 ± 0.63 y

ab, xy. Means within season followed by the same letter are not significantly different (P > 0.05).

Table 7. Seasonal comparison of primary productivity (g C/m³ per day) and community respiration (g C/m³ per day) in ponds fertilized with chicken litter or chemical fertilizer during Cycle II.

Treatment	Net primary productivity	Gross primary productivity	Community respiration
Chicken Litter			
Dry season	3.40	1.44	4.02
Rainy season	5.58	1.89	7.38
Chemical Fertilizer			
Dry season	2.82	1.38	2.87
Rainy season	3.54	1.21	4.66
Treatment means			
Chicken litter	4.71*	1.71*	6.04*
Chemical fertilizer	3.25	1.28	3.94
Seasonal means			
Dry season	3.11*	1.41	3.45*
Rainy season	4.56	1.55	6.02

* Means are significantly different ($P \leq 0.05$).

Table 8. Summary of nitrogen, phosphorus, and potassium contents (% dry matter), percent total solids (TS) of nutrient sources, and nutrient application rates during Cycle II dry and rainy seasons.

Nutrient source	Nitrogen (%)	Phosphorus (%)	Potassium (%)	TS (%)	Application rate (kg TS/ha per week)	Total application	
						Nitrogen (kg/ha)	Phosphorus (kg/ha)
<u>Dry Season</u>							
Layer chicken litter	2.75	2.46	2.33	83.3	500	302	270
Dairy cow manure	1.46	0.55	0.70	21.3	1020	328	123

Figure 1. Growth of *Oreochromis niloticus* (10,000 males/ha) during the Cycle II dry season experiment.

Figure 2. Growth of *Oreochromis niloticus* (10,000 males/ha) during the Cycle II rainy season experiment.

Figure 3. Mean total alkalinity in ponds during the Cycle II dry season experiment.

Figure 4. Mean total alkalinity in ponds during the Cycle II rainy season experiment.

Figure 5. Mean total hardness in ponds during the Cycle II dry season experiment.

Figure 6. Mean total hardness in ponds during the Cycle II rainy season experiment.

Figure 7. Mean ammonia-nitrogen concentrations in ponds during the Cycle II dry season experiment.

Figure 8. Mean ammonia-nitrogen concentrations in ponds during the Cycle II rainy season experiment.

Figure 9. Mean soluble orthophosphate concentrations in ponds during the Cycle II dry season experiment.

Figure 10. Mean soluble orthophosphate concentrations in ponds during the Cycle II rainy season experiment.

Figure 11. Mean total phosphorus concentrations in ponds during the Cycle II dry season experiment.

Figure 12. Mean total phosphorus concentrations in ponds during the Cycle II rainy season experiment.

Figure 13. Mean early morning dissolved oxygen concentrations in ponds during the Cycle II dry season experiment.

Figure 14. Mean early morning dissolved oxygen concentrations in ponds during the Cycle II rainy season experiment.

Figure 15. Mean weekly chlorophyll *a* concentrations in ponds fertilized with organic and inorganic fertilizer during the Cycle II rainy season experiment.

Figure 16. Relationship between tilapia yield and community respiration in ponds during the Cycle II dry season experiment.

Figure 17. Relationship between tilapia yield and gross primary productivity in ponds during the Cycle II rainy season experiment.

Figure 18. Relationship between tilapia yield and net primary productivity in ponds during the Cycle II rainy season experiment.

Figure 19. Relationship between tilapia yield and community respiration in ponds during the Cycle II rainy season experiment.

Figure 20. Relationship between gross primary productivity and Secchi disk visibility in ponds during the Cycle II rainy season experiment.

**APPENDIX. Complete Set of Data from Cycle II of the Pond/Dynamics
Aquaculture CRSP in Honduras.**
